A jet engine may contain internal airflow pockets or plenums, which are used to cool components or may be used for other purposes. The plenums may be generated by pressure differentials within the engine or by size variations in the engine, such as in the upstream manifold or in the aft (aft exhaust gases). In current engines, these plenums are usually cut by hand or by machines and welded to the pressure boundaries of the engine. This process can be time consuming and can be very expensive. In addition, tolerances between the plenums and the engine may result in a gap or leak between the plenums and the engine. This gap or leak may result in leakage of fluids from the engine, such as cooling water. Leaking of fluid results in the need for engine maintenance and repair of the engine, which is undesirable. Further areas of applicability will become apparent from the description provided herein. The description and specific examples in this summary are intended for purposes of illustration only and are not intended to limit the scope of the present disclosure. Corresponding reference numerals indicate corresponding parts throughout the several views of the drawings.

Q: how to write sql query to get min and max date for each user? I have a table with client info. I want to show the userid and the date of the most recent entry for each user. A: You can use a window function: `select userid, date, max(date) over (partition by userid) as max_date from yourtable`; You can use a subquery to get the most recent userid/date pair for each user. Then you can join that back to your table: `select t.* from yourtable t inner join (select userid, max(date) over (partition by userid) as max_date from yourtable group by userid) g on g.userid = t.userid and g.max_date = t.date`; Role of transient receptor potential canonical channels on the responses to thrombin in rat nodose ganglion neurons. The transient receptor potential canonical (TRPC) family is essential for the formation of many cellular processes, including cell proliferation, migration

The invention relates to a method for feeding a dendritic polyphosphate precipitate into a gas composition, and in particular a method for feeding a granular dendritic polyphosphate precipitate into a biological waste gas. Polyphosphates are the nutrient required for the growth of micro-organisms and were first discovered by the French scientist Clapeyron in 1838. Dendritic polyphosphates are polyphosphates which are structurally different from the chains known until now. A dendritic polyphosphate is built by atoms linked via phosphohate groups and it can have a linear, dendritic or comb-shaped structure, the configuration of which depends on the time of crystallization, the number of atoms linked and the pH-value of the solution. There are two different ways of producing these polyphosphates from polyhydroxyl compounds. The first known way is a so-called macromolecular synthesis in which a polyhydroxyl compound is reacted with an acid to produce sodium polyphosphate (SAP) in the case of monosodium polyphosphate (MSP) and disodium polyphosphate (DSP). A second known way is a so-called nucleophilic method in which a polyhydroxyl compound and a strong base are brought into contact and small
